A. Project Title

Phytophthora Root Rot of Chestnut Trees: Research Projects at Clemson University

B. Summary

We will continue to conduct independent research projects and collaborate with colleagues to better understand and manage Phytophthora root rot (PRR) on American and hybrid chestnut trees. In 2021, we will:

1. Continue to assay soils in the eastern United States for *Phytophthora* spp. and collect and store representative isolates in a permanent collection
2. Repeat an experiment to determine the efficacy of fungicides to manage PRR on American chestnut seedlings
3. Determine when zoospores of *P. cinnamomi* infect American chestnut seedlings
4. Collaborate with TACF and the USDA Forest Service to conduct the annual *P. cinnamomi* resistance screening experiment.

C. Principal Investigators and Institutional Affiliation

Steven N. Jeffers, Professor and Extension Specialist

Phone: 864-656-6704

D. Duration of Project: 01 November 2021 – 31 October 2022 = 12 months

E. Total Amount Requested: $9,958  
$5,228 = 52.5% Matching funds will be provided by Clemson University

F. Short- and Long-term Goals of Project

Short-term Goals

*Per Jared W, added $7000 RNA seq experiment—including histopathology work in collaboration with PSU Tatyana Z. Paid for with McQuaid Family Fdn grant issued for PSU.*
1. To continue to assay plant and soil samples, provided by TACF members, for species of *Phytophthora*, so we can identify where these plant pathogens are located in chestnut-growing sites and potential chestnut-growing sites in the eastern U.S.; then, culture and maintain representative isolates of *Phytophthora* spp. from chestnut-growing sites for future studies.

2. Complete an evaluation of commercially available fungicides that target Oomycetes for efficacy against Phytophthora root rot on American chestnut seedlings.

3. Determine when during the first 24 hours of exposure to zoospores of *P. cinnamomi* this pathogen establishes infection on American chestnut seedlings.

4. Identify and supply isolates recovered and stored in Goal 1 (above) for use in the annual TACF *P. cinnamomi* resistance screening experiment at the Resistance Screening Center (RSC) at USDA Forest Service Bent Creek Experimental Forest in Asheville, NC; then, assist with inoculating and scoring hybrid chestnut seedlings in spring and fall, respectively, during the year.

**Long-term Goals**

1. Identifying the location and distribution of *Phytophthora* spp., especially *P. cinnamomi*, is necessary, so TACF knows where it can and should not plant chestnut seedlings now and in the future. In addition, isolates of *Phytophthora* spp. recovered from diseased chestnut trees and infested soils will be maintained in a permanent collection at Clemson University, so that we can use them in future research projects—e.g., see Goal 4 below. This information is essential to breed chestnuts with resistance to all species of *Phytophthora* capable of causing Phytophthora root rot.

2. By identifying the most effective, commercially available fungicides for managing Phytophthora root rot on chestnut seedlings, we can work to get these products registered, so they can be legally applied to chestnuts seedlings and trees. We conducted one trial of this experiment in 2019 and now need to repeat it to validate results. We tried to repeat the experiment in 2020, but COVID restrictions hampered our efforts.

3. We have been collaborating with colleagues at the Pennsylvania State University (Tatyana Zhebentyayeva) and the University of Kentucky (Bert Abbott and Dana Nelson) to identify the genes involved in resistance to *P. cinnamomi*. By identifying when zoospores infect roots and establish a pathogenic relationship with chestnut seedlings, we can pinpoint when roots of both American and Chinese chestnut seedlings need to be harvested for RNA sequencing—so our colleagues can identify which genes are involved in the resistance processes in *Castanea* spp.

4. By staying actively involved in the annual TACF effort to screen hybrid chestnut seedlings for resistance to *P. cinnamomi*, we can maintain continuity and consistency in this effort, which our lab initiated in cooperation with Dr. Joe James in 2004. Next year, 2022 will be the 19th year of this resistance screening effort.

**G. Narrative**

**Introduction**
Phytophthora root rot (PRR) is a lethal disease of the American chestnut tree (Castanea dentata) that was killing trees in the southern range of this native forest tree species long before chestnut blight was reported in North America (Anagnostakis 2012, Crandall et al. 1945). Currently, the American Chestnut Foundation (TACF) has an active breeding program to develop backcross hybrid American chestnut trees with resistance to both Phytophthora cinnamomi, which causes PRR, and to Cryphonectria parasitica, which causes chestnut blight. Since 2003, our lab at Clemson University has worked in collaboration with TACF to study PRR, but we have lacked the financial support to maintain a consistent research effort necessary to make significant impacts in the etiology and management of this important disease. Despite a minimum of financial support, we have made considerable progress, and our collaboration with TACF has been productive (Westbrook et al. 2019, Zhebentyayeva, et al. 2019). In this proposal, I am requesting partial financial support for research projects we plan to conduct that support TACF efforts to restore the American chestnut tree to our eastern forests.

Assaying plant and soil samples for species of Phytophthora
We began isolating Phytophthora spp. from chestnut trees and soils in 2003 and have continued to provide this service to TACF ever since. Isolates recovered from chestnut trees, seedlings, and soils are maintained in a permanent collection in our lab at Clemson University. Over 19 years, we have processed hundreds of samples and have recovered Phytophthora spp. from 11 states—primarily in the southeastern and mid-Atlantic regions but also from a chestnut planting in southwestern Pennsylvania and recently from two sites in Missouri. Therefore, we now have a better understanding of the distribution of Phytophthora spp. in the native chestnut growing regions of the eastern U.S. We have isolated P. cinnamomi primarily from these samples, but occasionally we isolate other species. Based on our isolation efforts, we have confirmed PRR on chestnut seedlings or questioned the role of P. cinnamomi in seedling death of many plant samples sent to our lab for processing. We have confirmed the presence of P. cinnamomi in numerous chestnut planting sites or potential planting sites, which has prevented the death and loss of many valuable chestnut seedlings. To preserve American chestnut germplasm, TACF Chapters are trying to save representative seedlings and cuttings of surviving American chestnut trees. Often, these are preserved in GCOs located in states throughout the native range of the American chestnut. Before establishing a GCO, it is important to identify a site where P. cinnamomi is not present to prevent PRR on the planted material, which eventually will die if infected. Soil and plant samples are assayed using standard isolation protocols that have been developed in my lab over many years of studying Phytophthora spp. associated with fruit and ornamental crops (Ferguson and Jeffers 1999, Jeffers and Martin 1986).

Maintaining isolates of Phytophthora spp. in a permanent collection
Representative isolates of Phytophthora spp. recovered from plant and soil samples are maintained in a permanent collection in our lab, so they are available for futures studies and projects. Ove the years, we have identified five species of Phytophthora associated with chestnut trees, seedlings and soils: P. cinnamomi, P. cambivora, P. cryptogea, P. heveae, and P. quercetorum (Sharpe 2017). Before our study, only P. cinnamomi had been associated with American chestnut trees (Crandall et al. 1945, Westbrook et al. 2019). We currently have
several hundred isolates already in our collection and will continue collecting new isolates over the coming years. Eventually, we would like to characterize the diversity of the population of Phytophthora spp. associated with American chestnut. Eventually, the TACF breeding program will need to incorporate these other species into the annual screening procedure to be sure hybrid chestnut seedlings are resistant to all species of Phytophthora present in eastern forests.

**Identifying effective fungicides for managing PRR on American chestnut seedlings**

There are numerous commercially available fungicides that target Phytophthora spp. and other Oomycete plant pathogens. However, only products containing the active ingredient mono- and di-potassium salts of phosphorous acid are registered for applications to chestnut trees (e.g., Reliant, Fosphite). TACF Chapters are trying to collect and preserve diverse populations of surviving American chestnut trees in GCOs, but it is very likely these plants are susceptible to PRR. Therefore, if *P. cinnamomi* or another pathogenic species of Phytophthora is present in the soils where GCOs are located, these pathogens could attack and kill all the trees in the orchard. Consequently, we conducted a greenhouse experiment in 2019 to evaluate the efficacy of eight commercially available fungicide products registered to manage Phytophthora diseases; each product contained a different active ingredient. Results from this experiment were very encouraging (Jeffers et al. 2019). Reliant, Aliette, and Subdue Maxx provided the best protection, but other products also were effective. This experiment needs to be repeated to validate and confirm these results. Eventually, we will need to seek registrations for products with the most effective active ingredients, so these products can be used legally to protect chestnut trees growing in Phytophthora-infested soils.

**Determine when zoospores of *P. cinnamomi* infect chestnut seedlings**

We will conduct an experiment to determine when American chestnut seedlings become infected during the first 24 hours of exposure to zoospores of *P. cinnamomi*. Seedlings will be grown in the greenhouse in Deepots (Stuewe and Sons, Inc., Tangent OR) containing soilless container mix (Fafard 3B: Sun Gro Horticulture, Agawam, MA) or particulate field conditioner (Turface MVP: Profile Products LLC, Buffalo Grove, IL). Seedlings will be removed from the pots, and the substrate will be washed from the roots. Seedlings then will be submerged in 50 liters of a zoospore suspension in 60-liter tubs (Fig. 1).

![Figure 1. American chestnut seedlings suspended in a suspension of *P. cinnamomi* zoospores. Washed roots are submerged in the suspension.](image-url)
Seedlings will be removed from the suspension at 3, 6, 12, and 24 hours after initial exposure, roots will be surface disinfested in a sanitizer solution for 30 sec and rinsed under running water, and seedling roots will be placed in clean tap water for up to 7 days for symptoms of PRR to develop. After 7 days in water, we will isolate from representative roots of each plant to determine the degree of infection. Rhododendron leaf disk baits also will be floated in the tubs and removed at each time point to verify zoospore activity throughout the experimental period.

Annual TACF effort to screen hybrid chestnut seedlings for resistance to *P. cinnamomi*

In cooperation with Dr. Joe James, my lab at Clemson University initiated a project to screen American, Chinese, and hybrid chestnut seedlings for resistance to *P. cinnamomi* in 2004. That project has continued annually ever since, and now is conducted in cooperation with the USDA Forest Service at the RSC at Bent Creek Experimental Forest in Asheville, NC. Each year, the site where surviving seedlings from the annual trial will be planted in the field is selected. This site is based on soil samples collected from potential sites in the Mid-Atlantic and Southeastern states. Soil samples are processed in our lab to identify ones that contain *P. cinnamomi*. Isolates of this pathogen are subcultured and maintained in axenic culture in a permanent collection. Once the field site for out-planting surviving seedlings is identified, we provide appropriate isolates of *P. cinnamomi* for inoculum production by Dr. Katie McKeever at the RSC. Staff from my lab then participate in inoculation of seedlings in the spring and scoring seedlings for root rot severity in the fall. Our involvement helps maintain continuity and consistency in how seedlings are inoculated and rated in this annual evaluation.

**I. Measurement and Reporting of Results**

Projects will be conducted based on the timeline above. Data will be collected as it becomes available—i.e., after samples are received and assayed and at the ends of trials. Likewise, these data will be summarized and analyzed when results are available. An annual report will be prepared in a timely manner based on results obtained in the 12-month period covered by the proposal. Progress and results to date will be presented at NE-1833 Meetings. Once a project has been completed and if data are based on replicated trials, results will be published in the *Chestnut* or other suitable peer-reviewed journal.
## J. Budget: One Year (Nov 2021 – Oct 2022)

### Budget Justification

**Amount Requested from TACF**
Funds are requested to cover 15% of the salary and fringe benefits for Mr. Linus Schmitz, the Lab Manager and Research Associate who is managing and working on these projects. Mr. Schmitz makes $18.00/hour and works 40 hours/week ($37,440 annual salary). The remainder of the funds will be used to pay for expendable lab supplies.

Expendable lab supplies for this project will be primarily laboratory materials used for isolation from plants and soil, isolate identification, and culture storage—e.g., disposable petri dishes, disposable multi-well plates, agar media, chemicals, medium amendments, PCR primers, centrifuge tubes, glass storage vials, etc.

**Matching funds provided by Clemson University**
TACF has a policy to not pay overhead (F&A – Facilities and Administration) charges because their grants are relatively small—see accompanying document. Therefore, this amount ($5,228) is used as matching funds from Clemson University.
K. Brief CV for each of the Principal Investigators

Steven N. Jeffers, Ph.D. – Abbreviated CV

Dept. of Plant and Environmental Sciences
105 Collings St., 214 BRC; Clemson University; Clemson, SC 29634-0310
Phone: 864/656-7157 • e-mail: sjffrs@clemson.edu

Education
1980: Cornell University, Ithaca, NY: M.S. Plant Pathology (Soil Science minor)
1976: University of California, Davis: B.S. (Highest Honors) Plant Science/Pomology

Employment
Clemson University, Clemson, SC
2007-present: Professor – Dept. of ESPS; School of Agriculture, Forestry, and Environmental Sciences; Dept. of Agricultural and Environmental Sciences; Dept. Plant and Environmental Sciences (currently)
2001-2007: Associate Professor – Depts. PP&P; Entomology, Soils, and Plant Sciences (ESPS)
1995-2001: Assistant Professor – Dept. of Plant Pathology and Physiology (PP&P)
EcoScience Corporation, Worcester, MA: 1992-1995; Senior Scientist
University of Wisconsin-Madison: 1985-1992: Assistant Professor, Dept. of Plant Pathology

Research Experience
1995-present: Development of integrated management strategies for diseases of ornamental crops and trees in South Carolina; biology and ecology of Phytophthora spp. in nurseries, greenhouses, landscapes, and natural ecosystems; management of rust diseases
1992-1995: Development of biological control products for postharvest diseases of fruit crops

Extension Experience
1995-present: Clemson University Extension Specialist, Diseases of Ornamental Crops & Trees
1985-1992: University of Wisconsin Extension Specialist, Diseases of Fruit Crops
